Abstract—Predicting student academic performance is one of the important applications in data mining in education. However, existing work is not enough to identify which factors will affect student performance. Information on academic values or progress on student learning is not enough to be a factor in predicting student performance and helps students and educators to make improvements in learning and teaching. K-Nearest Neighbor is a simple method for classifying student performance, but K-Nearest Neighbor has problems in terms of high feature dimensions. To solve this problem, we need a method of selecting the Gini Index feature in reducing the high feature dimensions. Several experiments were conducted to obtain an optimal architecture and produce accurate classifications. The results of 10 experiments with values of k (1 to 10) in the student performance dataset with the K-Nearest Neighbor method showed the highest average accuracy of 74.068 while the K-Nearest Neighbor and Gini Index methods showed the highest average accuracy of 76.516. From the results of these tests it can be concluded that the Gini Index is able to overcome the problem of high feature dimensions in K-Nearest Neighbor, so the application of the K-Nearest Neighbor and Gini Index can improve the accuracy of student performance classification better than using the K-Nearest Neighbor method.

Keywords: K-Nearest Neighbor, Gini Index, Student Performance

Intisari—Memprediksi kinerja akademik siswa adalah salah satu aplikasi penting dalam data mining bidang pendidikan. Namun, pekerjaan yang ada tidak cukup untuk mengidentifikasi faktor mana yang akan mempengaruhi kinerja siswa.

Informasi nilai akademik atau kemaiuan pembelajaran siswa saja tidak cukup untuk dijadikan faktor dalam memprediksi kinerja siswa serta membantu para siswa dan pendidik untuk melakukan perbaikan dalam pembelajaran dan pengajaran. K-Nearest Neighbor merupakan metode yang sederhana untuk klasifikasi kinerja siswa, namun K-Nearest Neighbor memiliki masalah dalam hal dimensi fitur yang tinggi. Untuk menyelesaikan masalah tersebut diperlukan metode seleksi fitur Gini Index dalam mengurangi dimensi fitur yang tinggi. Beberapa percobaan dilakukan untuk mendapatkan arsitektur yang optimal dan menghasilkan klasifikasi yang akurat. Hasil dari 10 percobaan dengan nilai k (1 sampai dengan 10) pada dataset *student performance* dengan metode K-Nearest Neighbor didapatkan rata-rata akurasi terbesar yaitu 74,068 sedangkan dengan metode K-Nearest Neighbor dan Gini Index didapatkan rata-rata akurasi terbesar yaitu 76,516. Dari hasil pengujian tersebut maka dapat disimpulkan bahwa Gini Index mampu mengatasi masalah dimensi fitur yang tinggi pada K-Nearest Neighbor, sehingga penerapan K-Nearest Neighbor dan Gini Index dapat meningkatkan akurasi klasifikasi kinerja siswa yang lebih baik dibanding dengan menggunakan metode K-Nearest Neighbor saia.

Kata Kunci: K-Nearest Neighbor, Gini Index, Kinerja Siswa

INTRODUCTION

Predicting student academic performance is one of the important applications in data mining in education (Altujjar, Altamimi, Al-Turaiki, & Al-Razgan, 2016). Student performance prediction

systems at an early stage can be very useful to guide student learning. Predicting student performance can help identify weak students (Pandey & Taruna, 2016) and enable academic institutions to provide appropriate support for students who face difficulties(Altujjar et al., 2016). In order for the prediction model to be truly useful as an effective aid for learning, the prediction model must provide a tool to interpret progress adequately, to detect trends and patterns of behavior and to identify the causes of learning problems (Villagrá-Arnedo et al., 2017). However, there is not enough work to identify which factors will influence its performance, in which ways students can make progress, and whether students have the potential to do better (Yang & Li, 2018). Student academic information becomes one of the factors of an educator's assessment in predicting student performance, but the academic value factor alone is not sufficient in predicting student performance. Information on student learning progress is not enough as an indicator of students and educators to make improvements in teaching and learning (Yang & Li, 2018). Social, personal and academic factors also influence in predicting student performance in schools (Fernandes et al., 2019).

The most popular technique for predicting student performance is data mining(Shahiri, Husain, & Rashid, 2015). Classification is a technique that is widely used to predict student performance (Altujjar et al., 2016) Several studies with classification techniques have been carried out, such as Artificial Neural Networks (Alkhasawneh & Hobson, 2011), Regression (Conijn, Snijders, Kleingeld, & Matzat, 2017), Support Vector Machine (Al-Shehri et al., 2017), Decision Tree (Lopez Guarin, Guzman, & Gonzalez, 2015), Naive Bayes (Lopez Guarin et al., 2015), dan K-Nearest Neighbor (Pandey & Taruna, 2016).

The K-Nearest Neighbor classification is a well-known pattern recognition method that has been used extensively in several applications (Cover & Hart, 1967) and has attracted wide interest in the research community(Gou et al., 2014) (Lin, Li, Lin, & Chen, 2014) (Lin et al., 2014). K-Nearest Neighbor is a method that is able to solve classification problems, has significant advantages and often produces competitive results from several other data mining methods(Adeniyi, Wei, & Yongquan, 2016). The simplicity of the K-Nearest Neighbor is its main virtue, which allows the classification of two or more patterns based on fairly simple rules(Han, Kamber, & Pei, 2012).

K-Nearest Neighbor is a simple method but because of its simplicity, the k-NN method has several problems that must be faced, the main problem is related to the high dimension of

features (López & Maldonado, 2018). K-Nearest Neighbor also has several drawbacks, namely the complexity of computing the similarity of large data. To reduce the complexity of K-Nearest Neighbor can be done by one method, namely by reducing the dimensions of high features (de Vries, Mamoulis, Nes, & Kersten, 2003). High feature dimensions are not permitted for many learning algorithms (Shang et al., 2007). Dimension reduction is very important in pattern formation (López & Maldonado, 2018).

The main problem in classification is that high feature dimensions can be overcome by feature selection methods namely Gini Index (Shang et al., 2007) Using the right feature selection method can improve classification performance (Wang, Li, Song, Wei, & Li, 2011) and improve accuracy (Xu, Peng, & Cheng, 2012). Feature selection performs high feature reduction by removing irrelevant attributes (Koncz & Paralic, 2011). The Gini Index is used to separate attributes and get better classification accuracy (Shang et al., 2007). Gini Index is applied for feature selection and weight adjustment (Shankar & Karypis, 2000). Compared to other feature selection methods, the Gini Index shows better classification performance (Shang et al., 2007).

This explanation explained that the Gini Index has good potential in reducing the high dimension of features. Therefore in this study will use a combination of the two methods namely K-Nearest Neighbor and Gini Index to improve accuracy in the classification of student performance.

MATERIALS AND METHODS

Material

The student performance dataset obtained from the UCI Machine Learning Repository was used in this study. The student performance dataset consists of 30 attributes and 1 class. Table 1 shows the attributes and their description. Table 2 shows the attributes, data, and description of the data.

Metode

Figure 1 shows the proposed K-Nearest Neighbor and Gini Index methods in this study. At the pre-processing stage, feature selection is performed using the Gini Index method so that it produces a new dataset with the most optimal attributes. Then the new dataset is divided into training data and testing data with the 10 Fold Cross Validation method. Then the training data is classified using the K-Nearest Neighbor method. The final step of testing data is tested by looking at performance accuracy.

K-Nearest Neighbor

K-Nearest Neighbor is an effective, intuitive and simple method (Gou et al., 2014)(Lin et al., 2014). In pattern recognition, the K-Nearest Neighbor algorithm is a non-parametric method that is useful for grouping objects based on close features. The K-Nearest Neighbor concept is a label or class determined by the majority vote of its neighbors (Won Yoon & Friel, 2015). The working principle of K-Nearest Neighbor is to find the closest distance between the data that is evaluated with k nearest neighbors in the training data. The calculation equation to find Euclidean with d is distance and p is the data dimension, namely:

Where:

x1: sample test data d: distance x2: test data p: a dimension of data

Gini Index

Gini Index is the probability of two randomly selected data that have different classes. The Gini Index is used by Breiman (Breiman, 2001) to produce a classification tree in the decision tree. Suppose S is 1 set of number s data. This data has a number of different m classes (Ci, i = 1, ..., m). Based on the class, we can divide S into a number of m subsets (Si, i = 1, ..., m), for example, Si is a dataset incorporated in the Ci class, si is the amount of data from Si, then the Gini Index can be formulated as follows:

RESULTS AND DISCUSSION

Table 3 shows the results of the experiment, which is the comparison of the accuracy of the K-Nearest Neighbor method with the K-Nearest Neighbor and Gini Index on the classification of student performance using the student performance dataset. Table 3 shows the K-Nearest Neighbor method obtained the largest average accuracy is 74.068 while the K-Nearest Neighbor method and Gini Index obtained the largest average accuracy is 76.516.

Table 3 Comparison of Accuracy with K-Nearest
Neighbor with K-Nearest Neighbor and Gini Index

	Accuracy	
Experiment (k)	K-Nearest Neighbor	K-Nearest Neighbor dan Gini Index
1	68,96	72,41
2	62,55	67,24
3	75	75,96
4	72,6	74,62
5	76,34	77,78
6	76,34	78,07
7	77,58	79,12
8	77,11	79,22
9	77,1	80,75
10	77,1	79,99
Average	74,068	76,516

Source: (Setiyorini & Asmono, 2019)

The results of these experiments indicate that the Gini Index is able to overcome the problem of high feature dimensions in K-Nearest Neighbor so that the accuracy of the classification of student performance is better than using the K-Nearest Neighbor method alone. This proves the research of Shang et al. that the Gini Index is able to reduce high dimensional dimensions so that it gets better classification accuracy (Shang et al., 2007). The results also prove the research of Setiyorini and Asmono (Setiyorini & Asmono, 2017), that the Gini Index is an effective method to improve the performance of K-Nearest Neighbor so as to improve the accuracy of the cognitive level classification of problems in Bloom's Taxonomy.

CONCLUSION

The results of 10 experiments with a value of k (1 to 10) in the student performance dataset with the K-Nearest Neighbor method obtained the greatest average accuracy is 74.068 while the K-Nearest Neighbor and Gini Index methods obtained the largest average accuracy is 76.516. From the results of these experiments, it can be concluded that feature selection with the Gini Index is able to reduce the feature dimensions which are high so that the application of K-Nearest Neighbor and Gini Index can improve the classification accuracy of student performance better than using the K-Nearest Neighbor method alone.
